

# The Greedy Method Knapsack

Mark Matthews PhD

- ◆ **The greedy method** is a general algorithm design paradigm, built on the following elements:
  - **configurations**: different choices, collections, or values to find
  - **objective function**: a score assigned to configurations, which we want to either maximize or minimize
- ◆ It works best when applied to problems with the **greedy-choice** property:
  - a globally-optimal solution can always be found by a series of local improvements from a starting configuration.

# 0/1 Knapsack Problem

---

Maximum weight: 5lbs  
\$0 Dollars

	Weight	Value
Item 1	5 lbs	\$60
Item 2	3 lbs	\$50
Item 3	2 lbs	\$70
Item 4	1 lb	\$30

Write a program that selects a subset of items that has a maximum value within a given weight constraint

Limitations of Greedy Algorithms? They can fail to find the globally optimal solution because they only make decisions with limited information at each point (i.e., they can't consider all the options)

# The Fractional Knapsack Problem

- ◆ Given: A set  $S$  of  $n$  items, with each item  $i$  having
  - $b_i$  - a positive benefit
  - $w_i$  - a positive weight
- ◆ Goal: Choose items with maximum total benefit but with weight at most  $W$ .
- ◆ If we are allowed to take fractional amounts, then this is the **fractional knapsack problem**.
  - In this case, we let  $x_i$  denote the amount we take of item  $i$

- Objective: maximize 
$$\sum_{i \in S} b_i (x_i / w_i)$$

- Constraint: 
$$\sum_{i \in S} x_i \leq W$$

## Example

- ◆ Given: A set  $S$  of  $n$  items, with each item  $i$  having
  - $b_i$  - a positive benefit
  - $w_i$  - a positive weight
- ◆ Goal: Choose items with maximum total benefit but with weight at most  $W$ .

Items:					
Weight:	4 ml	8 ml	2 ml	6 ml	1 ml
Benefit:	\$12	\$32	\$40	\$30	\$50
Value: (\$ per ml)	3	4	20	5	50

"knapsack"

10 ml

Solution:

- 1 ml of 5
- 2 ml of 3
- 6 ml of 4
- 1 ml of 2

# The Fractional Knapsack Algorithm

---

◆ Greedy choice: Keep taking item with highest **value** (benefit to weight ratio)

■ Since  $\sum_{i \in S} b_i (x_i / w_i) = \sum_{i \in S} (b_i / w_i) x_i$

■ Run time:  $O(n \log n)$ . Why?

# The Fractional Knapsack Algorithm

- ◆ **Correctness:** Suppose there is a better solution
  - there is an item  $i$  with higher value than a chosen item  $j$ , but  $x_i < w_i$ ,  $x_j > 0$  and  $v_i < v_j$
  - If we substitute some  $i$  with  $j$ , we get a better solution
  - How much of  $i$ :  $\min\{w_i - x_i, x_j\}$
  - Thus, there is no better solution than the greedy one

**Algorithm** *fractionalKnapsack*( $S, W$ )

**Input:** set  $S$  of items w/ benefit  $b_i$   
and weight  $w_i$ ; max. weight  $W$

**Output:** amount  $x_i$  of each item  $i$   
to maximize benefit w/ weight at  
most  $W$

**for each item  $i$  in  $S$**

$x_i \leftarrow 0$

$v_i \leftarrow b_i / w_i$  {value}

$w \leftarrow 0$  {total weight}

**while  $w < W$**

*remove item  $i$  w/ highest  $v_i$*

$x_i \leftarrow \min\{w_i, W - w\}$

$w \leftarrow w + \min\{w_i, W - w\}$

# Task Scheduling

- ◆ Given: a set  $T$  of  $n$  tasks, each having:
  - A start time,  $s_i$
  - A finish time,  $f_i$  (where  $s_i < f_i$ )
- ◆ Goal: Perform all the tasks using a minimum number of “machines.”

# Task Scheduling Algorithm

- ◆ Greedy choice: consider tasks by their start time and use as few machines as possible with this order.
- Run time:  $O(n \log n)$ . Why?

## Algorithm *taskSchedule(T)*

**Input:** set  $T$  of tasks w/ start time  $s_i$  and finish time  $f_i$

**Output:** non-conflicting schedule with minimum number of machines

$m \leftarrow 0$  {no. of machines}

**while**  $T$  is not empty

*remove task  $i$  w/ smallest  $s_i$*

**if** *there's a machine  $j$  for  $i$*  **then**

*schedule  $i$  on machine  $j$*

**else**

$m \leftarrow m + 1$

*schedule  $i$  on machine  $m$*

- ◆ **Correctness:** Suppose there is a better schedule.
- We can use  $k-1$  machines
- The algorithm uses  $k$
- Let  $i$  be first task scheduled on machine  $k$
- Machine  $i$  must conflict with  $k-1$  other tasks
- But that means there is no non-conflicting schedule using  $k-1$  machines

## Example

- ◆ **Given: a set  $T$  of  $n$  tasks, each having:**
  - A start time,  $s_i$
  - A finish time,  $f_i$  (where  $s_i < f_i$ )
  - $[1,4], [1,3], [2,5], [3,7], [4,7], [6,9], [7,8]$  (ordered by start)
- ◆ **Goal: Perform all tasks on min. number of machines**

- ◆ Given a string  $X$ , efficiently encode  $X$  into a smaller string  $Y$ 
  - Saves memory and/or bandwidth
- ◆ A good approach: **Huffman encoding**
  - Compute frequency  $f(c)$  for each character  $c$ .
  - Encode high-frequency characters with short code words
  - No code word is a prefix for another code
  - Use an optimal encoding tree to determine the code words

## Encoding Tree Example

- ◆ A **code** is a mapping of each character of an alphabet to a binary code-word
- ◆ A **prefix code** is a binary code such that no code-word is the prefix of another code-word
- ◆ An **encoding tree** represents a prefix code
  - Each external node stores a character
  - The code word of a character is given by the path from the root to the external node storing the character (0 for a left child and 1 for a right child)

# Encoding Tree Optimization

- ◆ Given a text string  $X$ , we want to find a prefix code for the characters of  $X$  that yields a small encoding for  $X$ 
  - Frequent characters should have long code-words
  - Rare characters should have short code-words
- ◆ Example
  - $X = \text{abracadabra}$
  - $T_1$  encodes  $X$  into 29 bits
  - $T_2$  encodes  $X$  into 24 bits

## Huffman's Algorithm

---

- ◆ Given a string  $X$ , Huffman's algorithm constructs a prefix code that minimizes the size of the encoding of  $X$
- ◆ It runs in time  $O(n + d \log d)$ , where  $n$  is the size of  $X$  and  $d$  is the number of distinct characters of  $X$
- ◆ A heap-based priority queue is used as an auxiliary structure

## Example

$X = \text{abracadabra}$

# Procedure for Designing a Greedy Algorithm

---

1. Identify optimal substructure
2. Frame the problem as a greedy algorithm by using the greedy choice property (if possible)
3. Implement this with an iterative program

# Applications of Greedy Algorithms

---

- ◆ There are many applications for greedy algorithms such as:
  - ◆ Text compression (Huffman)
  - ◆ Graph search algorithms to compute the shortest path between 2 points - most famously as Dijkstra's algorithm
- ◆ For problems where greedy algorithms fail, dynamic programming is often a suitable choice
