EXERCISE

Given the following relational schema:

PROVIDES(Name_P, Product, Price)
ORDER(Order#, Date, Customer#)
INFO_ORD(Order#, Product, Quantity)
CUSTOMER(Customer#, Name, City)

where key attributes have been underlined: answer the questions.

- a) Can a provider provide more than one product?
- b) Can a given product be sold at different prices?
- c) Can two different orders with same number exist?
- d) Can a given product appear in two different orders?
- e) Express the following queries in relational algebra:
 - 1. Find the names of customers from Dublin that ordered Brie in 1999;
 - 2. Find the names of customers from Dublin that ordered both Brie and Parmesan Cheese in 1999;
 - 3. Find the names of customers that have ordered only Brie (i.e. all orders containing such customers contain Brie as product);

SOLUTIONS

- a) Yes
- b) Yes, but by different providers
- c) No
- d) Yes
- e.1) $\pi_{Name}(\sigma_F (CUSTOMER \bowtie ORDER \bowtie INFO_ORD))$

where:

F = Date<01/01/2000 AND Date>31/12/1998 AND City= 'Dublin' AND Product= 'Brie'

e.2) R= $\pi_{Name,Customer\#}$ (σ_F (CUSTOMER \bowtie ORDER \bowtie INFO_ORD))

where:

F = (Date<01/01/2000 AND Date>31/12/1998) AND City= 'Dublin' AND Product= 'Brie'

$$R_1 = \pi_{Name,Customer\#} (\sigma_{F1} (CUSTOMER) ORDER)$$

$$INFO_ORD))$$

where:

F1 = Date<01/01/2000 AND Date>31/12/1998 AND City= 'Dublin' AND Product= 'Parmesan'

Final result is $\pi_{\text{Name}}(R \cap R_1)$

e.3)

 $R = \pi_{Name, \ Customer\#} \ (\sigma_{Product = \ `Brie'} \ CUSTOMER \bowtie ORDER \bowtie INFO_ORD)$

 $R_1 = \pi_{Name, \ Customer\#} \ (\sigma_{Product <> \ `Brie'} CUSTOMER \bowtie ORDER \bowtie INFO_ORD)$

Final result is $\pi_{Name} (R - R_1)$
